

Training Report Day-7

13 June 2024

Object Oriented Programming in Python:

Object oriented programming approach allows us to club together the data and behavior so that it becomes easier to code real world scenarios.

Classes and Objects:

- Objects are real world entities. Anything you can describe in this world is an object.
- Classes on the other hand are not real. They are just a concept.

Classes are defined by using 'class' keyword.

```
class Mobile:  
    pass
```

To create an object, we need a class. The syntax for creating an object is "classname()", where classname is the name of the class.

```
Mobile()  
Mobile()  
Mobile()
```

Attributes of an Object:

Attributes are declared by using dot(.) operator with object.

Example:

```
class Mobile:  
    def __init__(self, brand, price):  
        self.brand=brand  
        self.price=price  
  
mob1=Mobile("Apple",20000)  
mob2=Mobile("Samsung",3000)
```

The diagram illustrates the class Mobile and its usage. The class Mobile is defined with an __init__ method that takes self, brand, and price as parameters. The __init__ method assigns self.brand=brand and self.price=price. Below the class definition, two objects are created: mob1=Mobile("Apple",20000) and mob2=Mobile("Samsung",3000). Arrows point from the labels 'Attributes' and 'Parameters' to the corresponding parts of the code.

Constructor & Self Introduction:

When we create an object, the special `__init__()` method inside the class of that object is invoked automatically. This special function is called as a constructor.

```
class Mobile:
    def __init__(self):
        print("Inside constructor")
mob1=Mobile()
```

`self` is not a keyword. `self` refers to the current object being executed.

```
class Mobile:
    def __init__(self):
        print("Id of self in constructor:", id(self))
mob1=Mobile()
id(mob1)
```

Parameterized constructor :

If a constructor takes parameters then it would be called as parameterized constructor.

```
class Mobile:
    def __init__(self, brand, price):
        print("Inside constructor")
        self.brand = brand
        self.price = price

mob1=Mobile("Apple", 20000)
print("Mobile 1 has brand", mob1.brand, "and price", mob1.price)

mob2=Mobile("Samsung",3000)
print("Mobile 2 has brand", mob2.brand, "and price", mob2.price)
```

```
class car:
    make = "hyundai"
    model = "verna"
    year = "2024"
obj1 = car()
print(obj1.make)
print(obj1.model)
print(obj1.year)
```

question 2

```
class person:
```

```
    name = ""
```

```
    age = 0
```

```
    def greet(self,a,b):
```

```
        name = a
```

```
        age = b
```

```
        print("hello",name,"you are",age,"years old")
```

```
obj2 = person()
```

```
obj2.greet("rahul",23)
```

question 3

```
class rectangle:
```

```
    length = 20
```

```
    breadth = 10
```

```
    def area(self):
```

```
        print(self.length*self.breadth)
```

```
obj3 = rectangle()
```

```
obj3.area()
```

question 4

```
class student:
```

```
    name = "lovin"
```

```
    grade = [80,80,70,90,60]
```

```
    def avg(self):
```

```
        grade = self.grade
```

```
        print(sum(grade)/len(grade))
```

```
obj4 = student()
```

```
obj4.avg()
```
